Edge Restraints for Interlocking Concrete Pavements

Introduction

Edge restraints are an essential component of interlocking concrete pavements. Restraints hold the pavers tightly together, enabling consistent interlock of the units across the entire pavement. They prevent spreading of the pavers from horizontal forces from traffic. Edge restraints are designed to remain stationary while receiving impacts during installation, from vehicles and from freeze-thaw cycles.

The following is a discussion of methods of restraining concrete pavers placed on bedding sand and installed on a flexible or rigid base.

Design Considerations

Restraints are required along the perimeter of interlocking concrete pavements or where there is a change in the pavement material. For example, when a laying pattern changes direction, there may be a need for an edge paver to act as a restraint (Figure 1). When a paver shape changes within an area of paver, the edge paver at the end of each pattern can serve as a restraint (Figure 2). Vertical walls of buildings can also provide a suitable restraint.

Some edge restraints require spiking to a flexible aggregate base. The rule of thumb is the base should extend beyond the restraint at least the same dimension as the thickness of the base material. For example, a 6 in. (150 mm) thick base should extend at least 6 in. (150 mm) beyond the spikes in the restraints. This contributes stability to the restraint especially in soils subject to heaving. Soil backfill is never a suitable edge restraint and edge restraints should never be installed on top of the bedding sand.

When installing an edge restraint on an existing rigid concrete base there are two methods typically used: direct fastened, or drilled and anchored. In a direct fastened system an explosive charge is used to drive the fastener into the solid concrete base. When using the drill and anchor method, holes must be drilled through the edge restraint (unless pre-drilled) and into the concrete to a sufficient depth. There are several “anchor” manufacturers and types available:

![Figure 1. Change in laying pattern direction.](image)

![Figure 2. Change in paver shape.](image)
1. Wedge Anchors,
2. Strike Anchors,
3. Drop-in Anchors,
4. Expansion Anchors.

When using direct fastened or drill and anchor system, it is important to consider several factors. When selecting materials consider the potential for galvanic corrosion created by using different metals. It may also be necessary to use a washer to prevent the fastener or anchor from pulling through the preformed hole in the edge restraint. Consult the fastener/anchor product information to ensure that you are utilizing the right charge and fastener/anchor for the application. Also consider the loads on the edge restraint when determining the spacing between each fastener/anchor. Also ensure that the proper Personal Protective equipment is utilized.

If there is a possibility of sand loss from beneath the pavers or between or under the joints of the edge restraints, geotextile is recommended to prevent its migration. A 12 in. (0.3 m) wide strip can be applied along the base and turned up along the sides of the restraints. Geotextile generally is not required across the entire surface of an aggregate base, nor should it be placed on top of the bedding sand.

**Types of Edge Restraints**

Table 1 shows the types of edge restraints and their application. There are two general types of edge restraints. Those made elsewhere and installed at the site include precast concrete, plastic, cut stone, aluminum and steel. Restraints formed onsite are made of poured in place concrete. Regardless of the material the edge restraint is made of, it should have a smooth vertical surface that will allow the side of the pavers to be in full contact with it.

**Manufactured Edge Restraints**

**Full depth precast concrete or cut stone** edging generally extends the depth of the base material. They can be set on compacted aggregate or concrete backfill (Figure 3).

**Partial depth precast concrete** edge restraints may be used for residential and light duty commercial applications. (Figure 4). These precast units are anchored on a compacted aggregate base with steel spikes. The spikes are typically 3/8 in. (10 mm) diameter. Depending on the design, the top of the concrete edge can be hidden or exposed.

**Plastic** edging installs quickly and will not rust or rot. Plastic edging should be specifically designed for use with pavers. It can be used with light duty residential and commercial applications, depending on the design. It should be firmly anchored into the compacted aggregate base course with spikes (See Figure 6). The spikes should penetrate well into the aggregate base. Spikes do not need to penetrate the bottom of the base. Consult the manufacturer’s literature for the recommended spacing of the spikes. **Edging for planting beds and flower gardens is not an acceptable restraint for interlocking concrete pavements.**

**Aluminum and steel** edging should be selected to provide a smooth vertical surface against the pavers. L-shaped edging provides additional stability. Stakes or spikes
fastened to the edging should be below the pavers or on
the outside of the restraints. Steel should be painted or
galvanized so that rust does not stain the pavers. Consult
manufacturer’s literature for recommended spacing of the
spikes. Spikes to secure aluminum edging should extend
well into the base course (Figure 5) or secured to the rigid
base. Like plastic edging, spikes used for aluminum edging
should never be placed into the soil. Aluminum and steel
edgings are manufactured in different thicknesses. The
thickest edging is recommended when pavers are subjected
to vehicular traffic.

Plastic or aluminum edge restraints can be used for
flexible or rigid bases. Steel edge restraints should only be
used on rigid bases. Do not use steel on flexible bases.

Timber is not recommended for an edge restraint be-
cause it warps and eventually rots.

Elevations should be set accurately for restraints that rest
on the base. For example, 2 3/8 in. (60 mm) thick pavers with 1
in. (25 mm) of bedding sand would have a base elevation set
3 in. (75 mm) below that of the finish elevation of the pavers.
This allows 1/4 in. (6 mm) settlement from compaction and
1/8 in. (3 mm) for minor settling over time. A minimum of 1
in. (25 mm) vertical restraining surface should be in con-
tact with the side of the paver to adequately restrain it. For
heavy duty application a greater restraining surface may be
warranted.

**Restraints Formed Onsite**

Poured in place concrete curbs or combination curb and
gutters required by municipalities make suitable restraints
for pavers. Exposed concrete edges should have a 1/4 in. to 1/8
(3 to 10 mm) radius edge to reduce the likelihood of chip-
service life. It is essential to the performance of the trowel reinforced mortar edge. Compacting units against troweled concrete should be done after the concrete has set. Care should be taken to ensure that the plate compactor does not crack the concrete edge or loosen pavers embedded in it. If the concrete is left to cure for a few days prior to compacting the pavers, the edges should be covered with plastic sheeting to prevent water from settling the uncompacted bedding sand. If water is allowed to enter bedding sand of any installation, it will be difficult to compact the pavers into it. The pavers will need to be removed, the saturated bedding sand removed, unsaturated sand installed, and the pavers replaced and compacted.

Caution shall be used when selecting troweled reinforced mortar in freezing climates as they may crack.

A concrete curb or edge that is “submerged” or hidden can be used to restrain concrete pavers. See Figure 9. The top surface of the concrete edge has pavers mortared to it. Acrylic fortified mortar is recommended and pavers...

Other Design Considerations

**Paver sidewalks against curbs**—Joints throughout poured in place or precast concrete curbs should allow excess water to drain through joints in them without loss of bedding sand. If there are no joints, weep holes placed at regular intervals will prevent the sand from migrating. A 1 in. (25 mm) diameter hole every 15 ft. (5m) is a recommended spacing. The bottom of the holes should be at the same elevation as the top of the base. They should be covered with filter cloth to prevent loss of bedding sand.

Joints in curbs often have expansion material in them.

Exposed to freeze-thaw and deicing salts should be applied with high-strength epoxy mortar materials. The minimum cross section dimensions of the curb should be 8 in. x 8 in. (200 mm x 200 mm). These dimensions apply to residential driveways and low volume streets. Larger sized curbs will be required in higher traffic areas or for support over weak soil. The concrete edge may require a layer of compacted aggregate base as a foundation. The width of concrete will need to be equal to the width of whole pavers mortared to it. This detail should not be used in heavy traffic areas such as major urban streets with regular truck or bus traffic.
This material tends to shrink and decompose. Filter cloth placed over these joints will prevent the sand from migrating. Expansion joint materials are not required between the pavers and the curb.

**Utility covers** in streets and walks (e.g., sewers, water and gas valves, telephone, electrical) should have concrete collars around them. Consistent compaction of aggregate base against cast iron collars is difficult, so a concrete collar placed around them after base compaction reduces the potential for settlement. Concrete collars should be 1/4 in. (6 mm) below the pavers to prevent catching snowplow blades (Figure 10). Drain and catch basin inlets should have a concrete collar around them if they are not encased in concrete.

When overlaying existing asphalt or concrete streets with pavers and bedding sand, utility covers are raised and new concrete collars poured around them. When raised, the covers and frames should be inspected for cracks that might allow migration of sand. Cracks should be repaired. Filter cloth should be applied on the base around the concrete collar, turned up against the collar to prevent sand loss.

**Catch basins**—During the early life of interlocking concrete pavement, there may be a need to drain excess water from the bedding sand. Drain holes may be drilled or cast into the sides of catch basins to facilitate this. The bottom of the holes are at the same elevation as the bottom of the base. Space holes at least 12 in. (0.3 m) apart, and make 1 in. (25 mm) in diameter. The holes should be covered with filter cloth to prevent loss of bedding sand. This drainage detail can prevent pumping and loss of bedding sand around the catch basin.

**Crosswalks**—Pavers in a crosswalk or abutting another pavement can be placed against a concrete beam (Figure 11), or a beam and slab base combination for pavements subject

to heavy vehicular traffic (Figure 12). The beam prevents horizontal creep of the pavers due to braking and turning tires. Figure 13 shows a light duty crosswalk appropriate for residential streets with minimal truck traffic. Refer to Tech Spec 19—Crosswalk Construction Using Interlocking Concrete Pavers for further details.

**Gutters and drainage channels** made with pavers should be embedded in fortified mortar, a bitumen-neoprene bed, or polymer adhesive. The mortar mix should resist degradation from freeze-thaw and salt. Care must be taken in applying the mortar as it can stain the pavers.

Sand is not recommended in joints subject to channelized water flow. The sand will eventually wash out of the paver joints and weaken the pavement. Cement can be dry mixed with joint sand (3% to 4% by weight) to reduce washout in areas subject to channelized drainage or from water draining from roof eaves without gutters. Care must be taken not to let the cement stain the pavers when sweeping the sand and cement into the joints. A more effective method is use of joint sand stabilization materials. Stabilizers are recommended to reduce risk of wash out on steep slopes. See ICPI Tech Spec 5—Cleaning, Sealing and Joint Sand Stabilization of Interlocking Concrete Pavement for more information.

**Elevations**—When edge restraints are installed before placing the bedding sand and pavers, the restraints are sometimes used to control thickness when screeding the bedding sand. Elevations for screeding should be set from the restraints after their elevations have been verified.

Attention should be given to the elevation of the pavers next to the restraints. Sand-set pavers may require a finish elevation of 1/4 in. (6 mm) above the top of the restraint. This allows for minor settlement of the pavers and surface drainage. Bitumen-set, mortared or adhesive-set pavers should be at least 1/4 in. (3 mm) above adjacent curbs or other edge restraints.

**Construction tips**—Some restraints allow the pavers and bedding sand to be installed prior to placing the edge materials. The field of pavers is extended past the planned edge location. The pavers are marked with a chalk line, or by using the edge material itself as large ruler for marking (Figure 14). The marked pavers are then cut with a powered saw or mechanical splitter. The unused ends and excess bedding sand are removed up to the cut pavers, and the edge restraints installed. This technique is particularly useful for creating curved edges.

When the gap between the pavers and the restraint...
exceeds 3/8 in. (10 mm), the space should be filled with cut pavers. Cut pavers exposed to vehicular traffic should be no smaller than one-third of the whole paver. The paving pattern may require shifting to accommodate cut pavers. Stability of cut edge pavers exposed to tire traffic is increased when a running course (string or sailor) of whole pavers is placed between the edge restraint or concrete collar and the cut edge pavers. Pavers are cut to fit against this edge course (see Figures 10 and 11). Other shapes include edge pavers that make a straight, flush edge. This detail can reduce incidental chipping of the cut pavers.

In some situations, site fixtures can be installed after the pavers are placed and vibrated and the joints filled with sand. Openings can be saw cut, the edge restraints placed, and the tree grates, bollards, or other fixtures installed.
